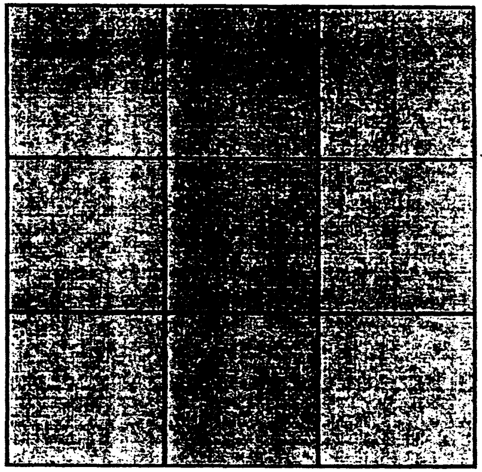
Mathematics and disaster relief: The hexayurt

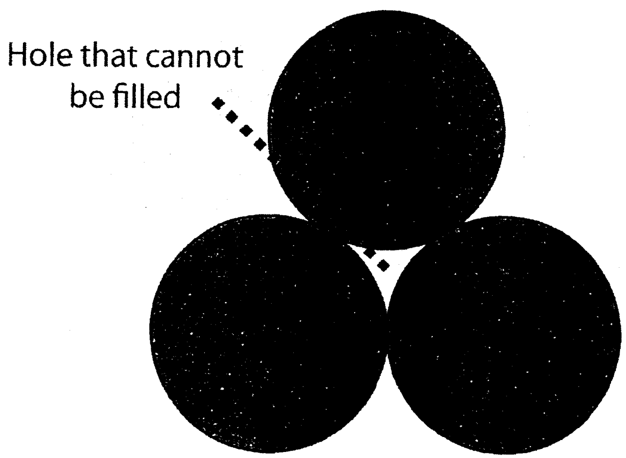
Vinay Gupta

www.hexayurt.com



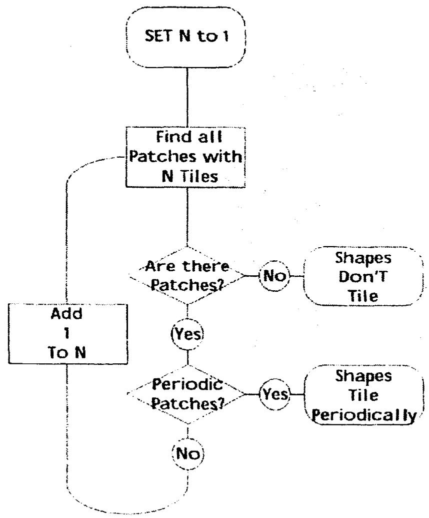
This can tile, periodically...

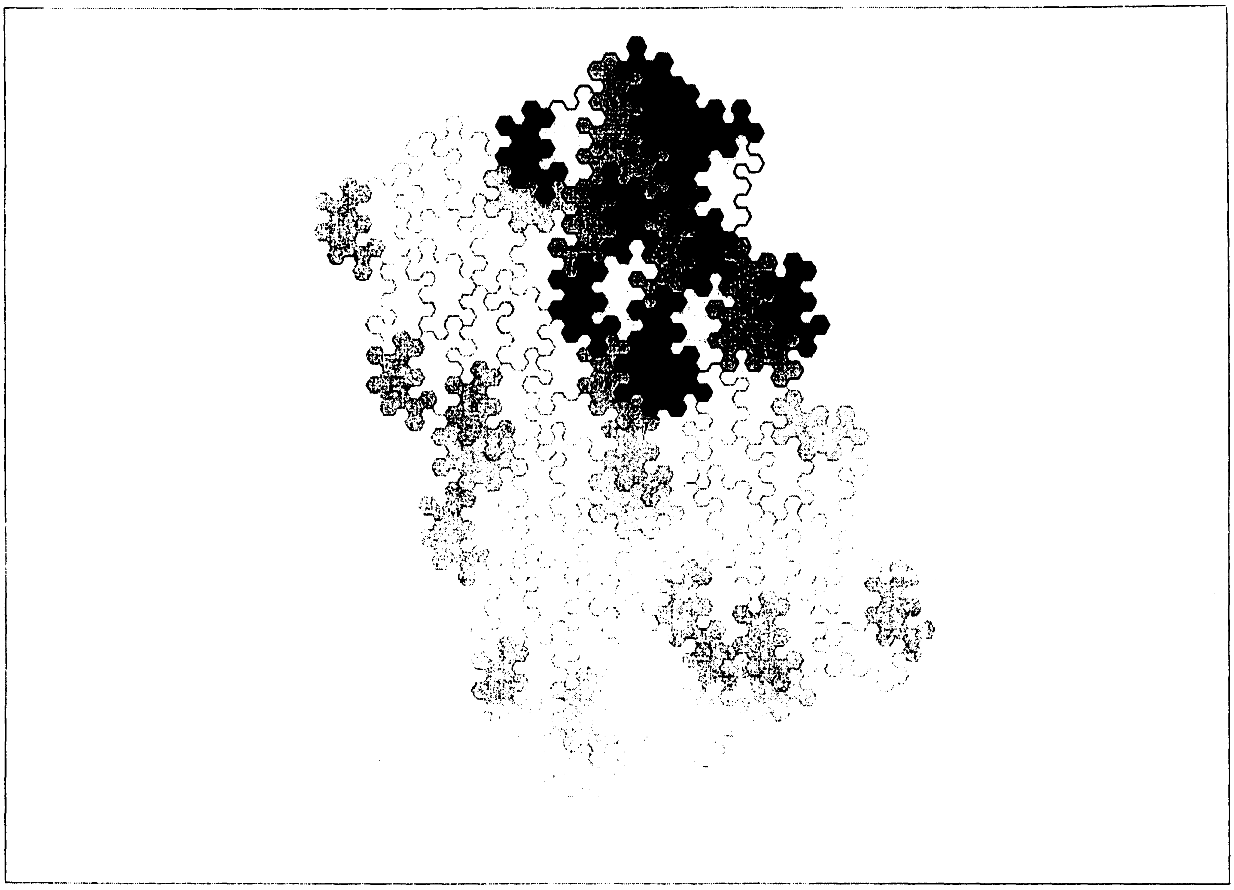
What about another, a circle...

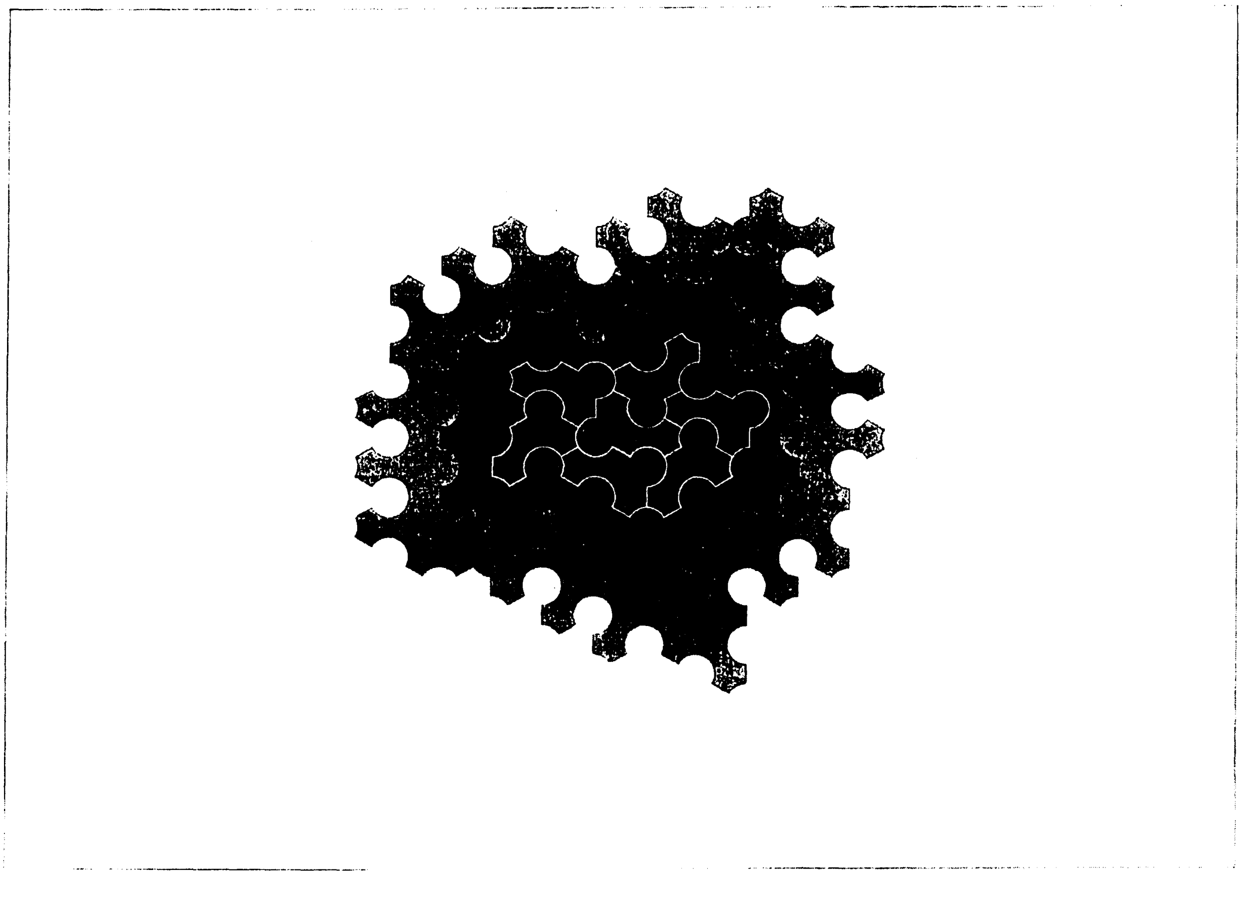


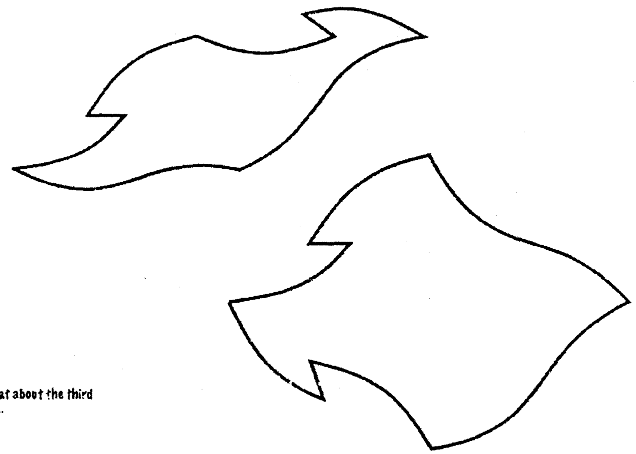
This clearly cannot tile, but maybe we have a simple algorithm...

Consider what happens for the tiles we have...







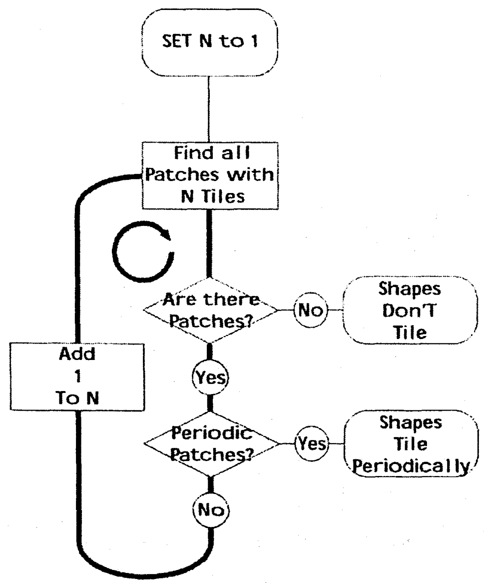


What about the third set...

This will run around the loop forever.

It gets worse. The question is undecidable

Whatever algorithm you find, there is always a set of shapes that will cause it to run forever without giving an answer...



Berger PhD Thesis

Simpler Proof: Robinson

Current state of the art:
5 Tiles Ollinger

This is a reminder of how deep undecidability cuts into mathematics.

(of course it is also exciting: simple questions about tilings will always yield interesting new ideas:

Like Aperiodicity...

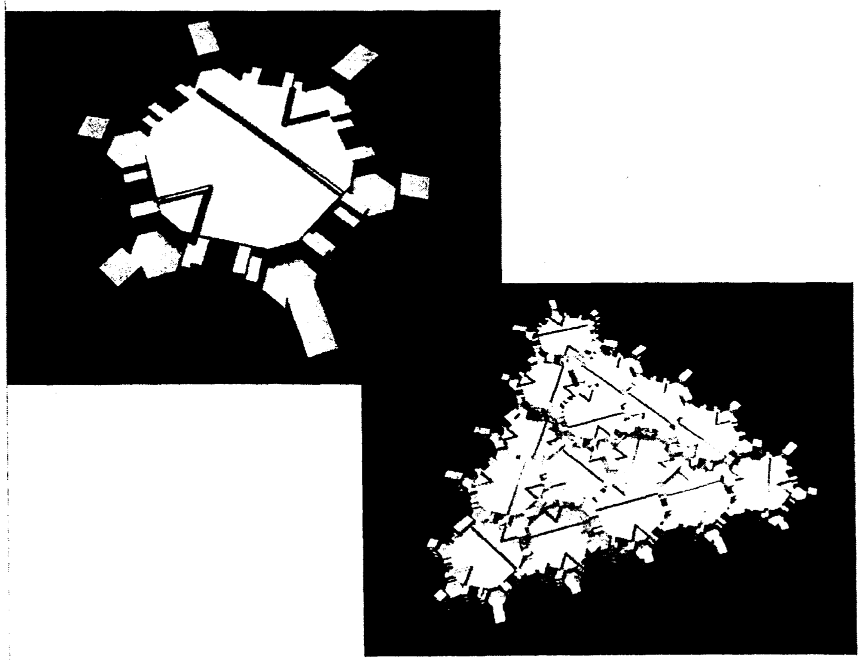
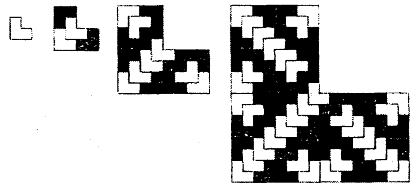
3d version, 1 periodic direction

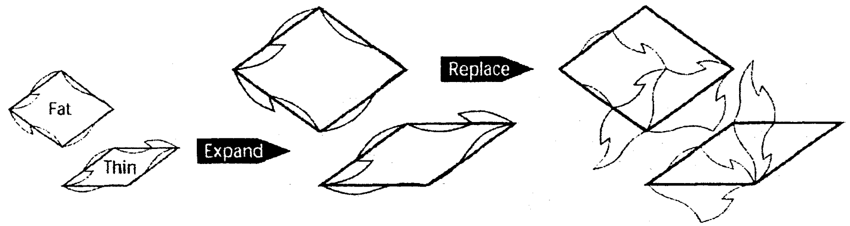
Mentioned in New Scientist

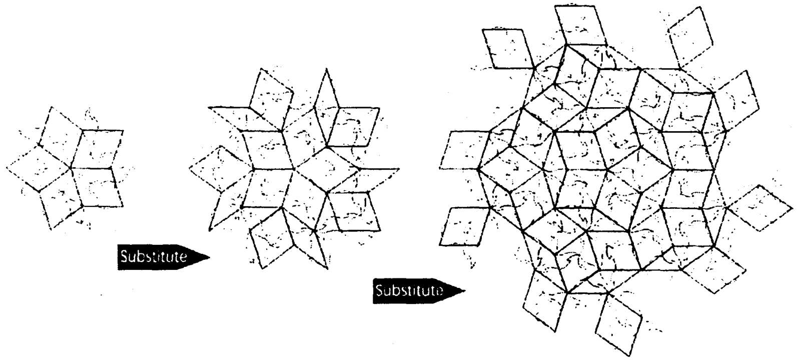
How can you tell if these shapes tile at all?

The answer is a substitution rule.







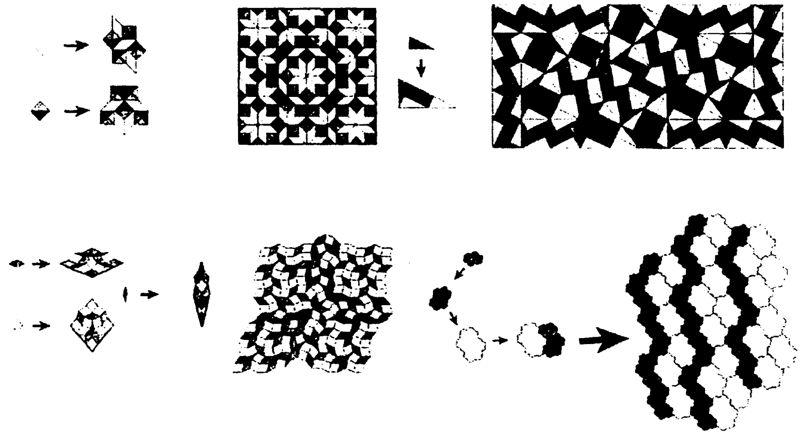


My work has been in creating and attempting to characterize substitution tilings.

The process of taking a substitution tiling

EG Penrose rhombs

and changing the edges to give a set of aperiodic tiles became known as matching rules...



A series of papers leading to a result that shows that we can get an aperiodic set of shapes from any substitution tiling…

Q. How?

This is an important result, but not well understood. So now…

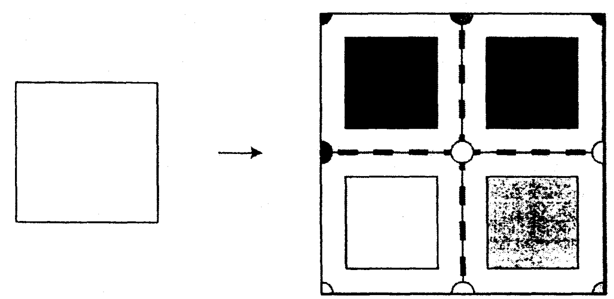
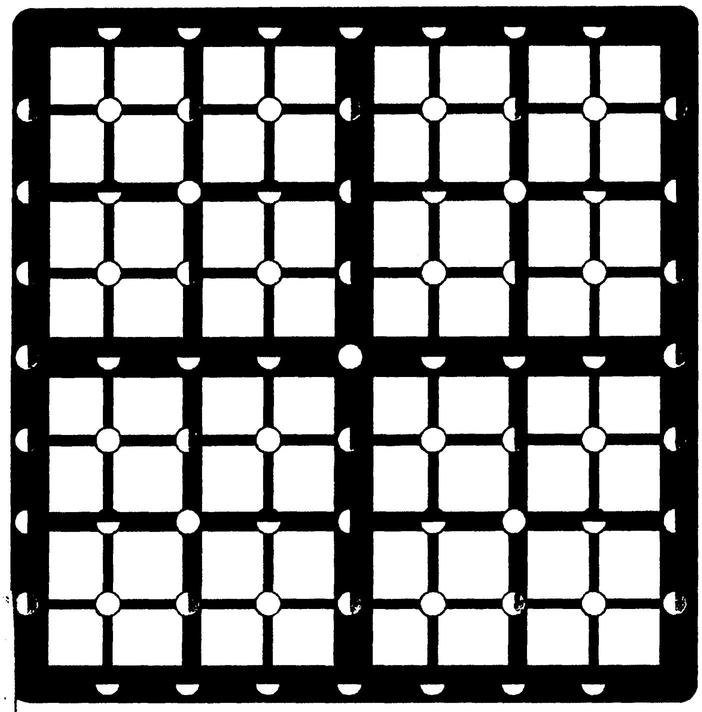
Start with the simplest possible substitution rule…

Label some features:

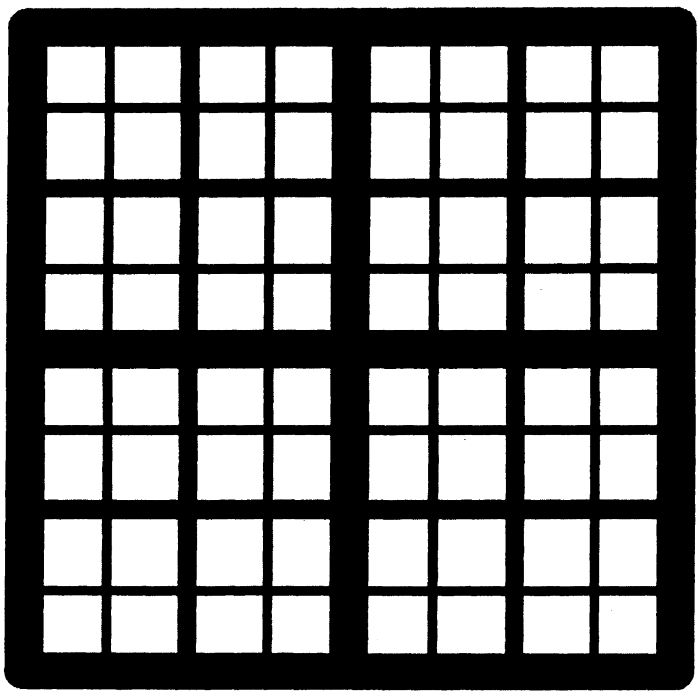
Edges, Vertices, Tiles





Some vertices will end up at the centre of a tile...

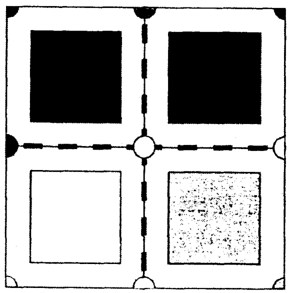
Others at the edge...

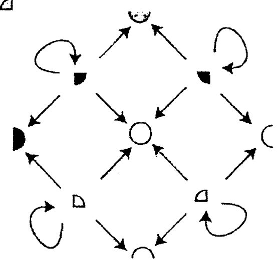


We can look at the hierarchy of the tiling.

Every edge ends up within a tile

We can build a graph to show the possible roles that a vertex can take.





Every Tile knows:

Its tile type

The eventual type of its special vertex

Every Edge knows:

Its eventual type

What supertile it lies in:

The tile type

The eventual type of its special vertex

Every Vertex knows

Its eventual type

What edges join it

What supertile it lies in:

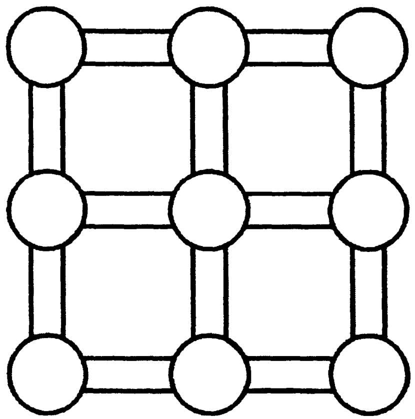
The tile type

The eventual type of its special vertex

We want this information on the objects. The key is edges, they can grow transporting the information around the tiling.

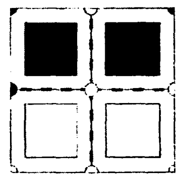
Now

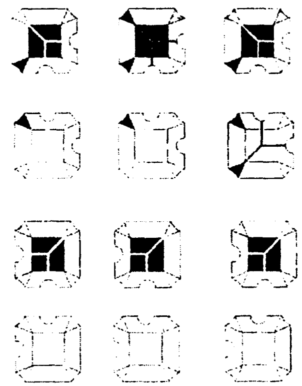
The tiles can be cut up to give the edges and vertices shape



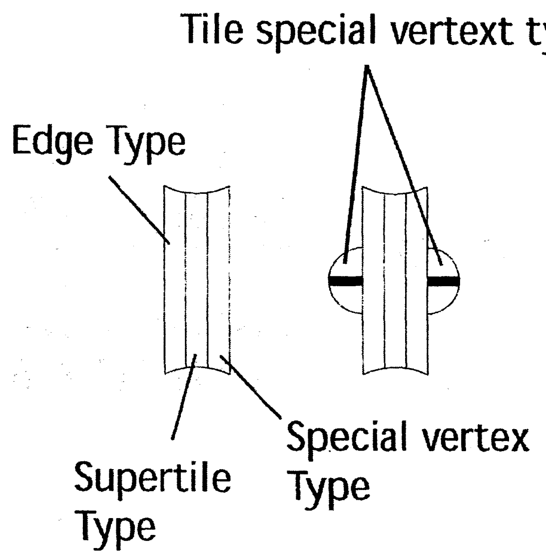
We can start with the tiles. Each knows its type and the type of its special vertex.

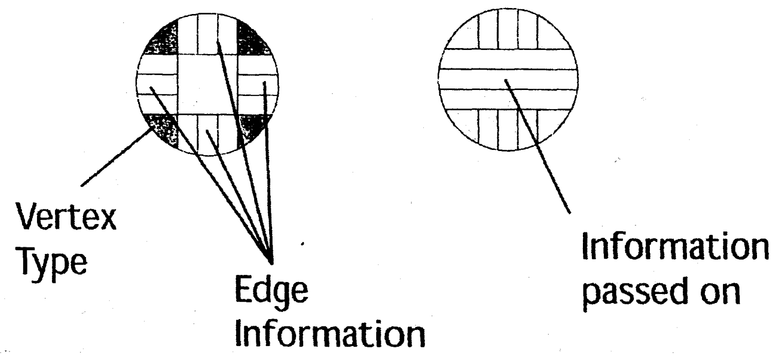
The edges of the supertile will also need to know the type of the special vertex, so the information is passed up to the internal edges.





Now look at edges. Each edge has three channels for the information it carries. There are also edges that plug into tiles.





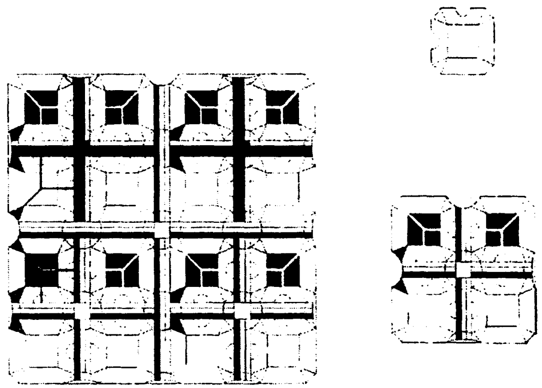
Lets build up a patch of tiling...

Note how the special vertex type is communicated up the hierarchy.

Thus each eleemnt can have finite information so there are a finite number of tiles...

but...

there are quite a few choices so...



We end up with a lot of tiles!

The nice thing is that the information that travels round is explicit.

All the interactions are local, yet some information is forced to travel arbitarily far. Something I at least find amazing.
